ABSTRACT OF THE DISCLOSURE

5

A fluidic apparatus and method for cooling a non-uniformly heated heat source such as an integrated circuit. The apparatus preferentially cools a non-uniformly heated integrated circuit. A coolant is introduced into a high-power region of the integrated circuit through an inlet. The coolant absorbs heat from this region and cools it.

Thereafter, the coolant is transferred to the low-power region of the integrated circuit.

After the coolant absorbs heat from the low-power region, it is removed from an outlet, which is connected to the low-power region of the integrated circuit.
